

AI Usage Log

1. AI Tool Used

AI Tool: ChatGPT, Gemini, Google Ai Studio

AI Tool was used as a learning and development support tool during the Android application development process.

2. Purpose of Using AI

The main purposes of using AI Tools were:

- To understand Android Studio and Kotlin programming concepts.
- To understand how Android components and Jetpack Compose can be used.
- To help identify and understand programming errors during development.
- To get suggestions for improving the mobile application's user interface.
- To explain programming concepts and code that were difficult to understand.
- To get small coding examples that could be studied and adapted.

AI was not used to generate the complete application or replace the team's own analysis and development work.

3. Representative Prompts

Examples of prompts used during the development process include:

1. "Explain how this Kotlin code works in simple terms."
2. "Why is this Android Studio code showing an error?"
3. "Explain how to create a form using Jetpack Compose."
4. "How can I validate user input in an Android application?"
5. "Give me some UI design ideas for a medical calculation application."
6. "Explain how navigation between Android screens works."

4. AI Suggestions Adopted

Some AI suggestions were used as references for learning and development. For example:

- Suggestions for organising the Android UI into separate sections.
- Suggestions for improving input validation.
- Suggestions for making error messages clearer.
- Small Kotlin or Jetpack Compose examples were used to understand implementation approaches.
- UI suggestions were considered when designing a cleaner and more user-friendly interface.

5. AI Suggestions Rejected or Modified

The AI-generated suggestions were not directly accepted without checking them.

Some suggestions were modified because they did not fully match the project requirements or the team's implementation. Code examples were also changed to fit the application's structure and requirements.

For the TDM calculation, the team did not rely on AI to create or decide the clinical formulas. The case study requires clinical equations and reference values to be supported by authoritative sources. Therefore, the calculation logic was reviewed and implemented based on the required project specifications and appropriate references.

6. Modifications Made by Students

All AI-assisted code and ideas were reviewed and modified by the team before being used.

Our group:

- Adjusted the code to match the application structure.
- Changed UI elements to fit the required workflow.
- Tested the code in Android Studio.
- Fixed errors that appeared during implementation.
- Checked that the application followed the case study requirements.
- Verified that the final implementation was understood by the team members.

7. Reflection

Using ChatGPT helped us learn Android development more efficiently, especially when we encountered unfamiliar Kotlin, Android Studio, and Jetpack Compose concepts. It was useful

for explaining errors and providing small examples that helped us understand how a solution could be implemented.

However, AI suggestions were treated only as learning support. We still needed to understand, modify, test, and verify the solutions ourselves. This helped us become more confident in explaining our implementation during the project demonstration and technical viva.

Overall, AI supported our learning and debugging process, but the final application design, implementation, testing, and technical decisions were completed and reviewed by the students.
